Chapter 1

Maxwell Equations

1.1 Lorentz Force

The force acting on a particle with electric charge q moving with velocity \mathbf{v} due to its interaction with electric and magnetic fields, \mathbf{E} and \mathbf{B} , is given by the expression

$$\mathbf{F} = q (\mathbf{E} + \mathbf{v} \times \mathbf{B}). \quad (1.1)$$

1.1.1 Electric Charge

The electric charge is measured in the units called *Coulomb* and the fundamental charge corresponds to that of an electron. Its value is

$$e = 1.602177 \times 10^{-19} \text{ C}. \quad (1.2)$$

The electric charge satisfies a superposition principle, so a set of n discrete point charges give a total electric charge given by

$$Q = \sum_{i=1}^n q_i. \quad (1.3)$$

Similarly, a continuous distribution of electric charge represented by a density function $\rho = \rho(t, \mathbf{r})$ over a volume V , gives a total charge

$$Q = \int_V \rho(t, \mathbf{r}) d^3r \quad (1.4)$$

1.1.2 Dirac Delta Function

In one dimension, the Dirac delta function has the properties:

1. $\delta(x - a) = 0$ for $x \neq a$

2. $\int \delta(x - a)dx = 1$ if the region of integration includes $x = a$ and is zero otherwise.
3. $\int f(x)\delta(x - a)dx = f(a)$
4. $\int f(x)\delta'(x - a)dx = -f'(a)$, where prime denotes derivative with respect to the argument.
5. $\delta(f(x)) = \sum_i \frac{1}{|\frac{df}{dx}(x_i)|} \delta(x - x_i)$ where $f(x)$ is assumed to have only simple zeros, located at $x = x_i$.
6. $\delta(ax) = \frac{1}{|a|} \delta(x)$
7. $x\delta(x) = 0$
8. $\delta(x^2 - e^2) = \frac{1}{2|e|} [\delta(x + e) + \delta(x - e)]$
9. $\delta(\mathbf{r} - \mathbf{R}) = \delta(x - X)\delta(y - Y)\delta(z - Z)$
10. $\int f(x)\nabla\delta(\mathbf{r} - \mathbf{r}_0)d^3x = -\nabla f|_{\mathbf{r}=\mathbf{r}_0}$
11. $\delta(\mathbf{r} - \mathbf{r}_0) = \delta(\mathbf{r}_0 - \mathbf{r})$

Example

For n point charges q_i moving along the trajectories $\mathbf{r}_i(t)$, the charge density may be written in terms of the Dirac delta function (see Appendix A) as

$$\rho(t, \mathbf{r}) = \sum_{i=1}^n q_i \delta(\mathbf{r} - \mathbf{r}_i(t)) \quad (1.5)$$

1.1.3 Electric Current

Electric charge in organized motion is called *electric current* and it is defined as

$$I = \frac{dQ}{dt} \quad (1.6)$$

and it is measured in units of *Coulomb per second* known as *Ampere*. The electric current can be written also as

$$I = \int \mathbf{j} \cdot d\mathbf{S} \quad (1.7)$$

where \mathbf{j} is the electric current density (current per unit area) and $d\mathbf{S} = \hat{\mathbf{n}}dS$ represents a surface element vector along which charge is moving.

1.1.4 Electric Charge Conservation and the Equation of Continuity

Consider a region of space with volume V and some amount of electric charge. If this charge moves away from this region, it will produce an electric current given by

$$I = -\frac{dQ}{dt}, \quad (1.8)$$

where the minus sign indicates that the charge in that region is decreasing (charge conservation). Introducing a current density, this can be written as

$$\oint \mathbf{j} \cdot d\mathbf{S} = -\frac{dQ}{dt}, \quad (1.9)$$

where the integration is considered over all the closed surface surrounding the volume in which the charge is located. This integral corresponds to the flux of electric charge across the closed surface. Now, using the concept of charge density we have

$$\oint \mathbf{j} \cdot d\mathbf{S} = -\frac{d}{dt} \int_V \rho d^3r \quad (1.10)$$

$$\oint \mathbf{j} \cdot d\mathbf{S} = -\int_V \frac{\partial \rho}{\partial t} d^3r \quad (1.11)$$

Using Gauss' theorem in the integral in the left hand side we transform the surface integral into a volume one,

$$\int_V \nabla \cdot \mathbf{j} d^3r = -\frac{d}{dt} \int_V \rho d^3r, \quad (1.12)$$

which gives the final result

$$\frac{\partial \rho}{\partial t} + \nabla \cdot \mathbf{j} = 0, \quad (1.13)$$

known as the *continuity equation*.

Example

Given the density function for a set of n point charges in Eq. (1.5) and the particles velocities $\mathbf{v} = \dot{\mathbf{r}}_i(t)$, we have

$$\frac{\partial \rho}{\partial t} = \sum_{i=1}^n q_i \frac{\partial}{\partial t} \delta(\mathbf{r} - \mathbf{r}_i) \quad (1.14)$$

$$\frac{\partial \rho}{\partial t} = \sum_{i=1}^n q_i \frac{d\mathbf{r}_i}{dt} \cdot \nabla_i \delta(\mathbf{r} - \mathbf{r}_i) \quad (1.15)$$

$$\frac{\partial \rho}{\partial t} = -\sum_{i=1}^n q_i \frac{d\mathbf{r}_i}{dt} \cdot \nabla \delta(\mathbf{r} - \mathbf{r}_i) \quad (1.16)$$

$$\frac{\partial \rho}{\partial t} = -\sum_{i=1}^n q_i \mathbf{v}_i \cdot \nabla \delta(\mathbf{r} - \mathbf{r}_i), \quad (1.17)$$

where the minus sign in the third line comes from the derivative properties of the delta function. Since $\nabla \cdot \mathbf{v}_i = 0$, we write

$$\frac{\partial \rho}{\partial t} = -\nabla \cdot \sum_{i=1}^n q_i \mathbf{v}_i \delta(\mathbf{r} - \mathbf{r}_i). \quad (1.18)$$

Comparison with the continuity equation (1.13) let us identify the corresponding density current as

$$\mathbf{j}(t, \mathbf{r}) = \sum_{i=1}^n q_i \mathbf{v}_i \delta(\mathbf{r} - \mathbf{r}_i). \quad (1.19)$$

1.1.5 Electric and Magnetic Fields

From Lorentz force (1.1) we identify the electric and magnetic fields,

$$\mathbf{E} = \mathbf{E}(t, \mathbf{r}) \quad (1.20)$$

$$\mathbf{B} = \mathbf{B}(t, \mathbf{r}). \quad (1.21)$$

The electric field is measured in units of *Newtons per Coulomb*, N/C while the magnetic field is measured in the units $\frac{N}{Cm/s} = \frac{N}{A \cdot m} = T$ known as *Tesla*. Electric fields are known to work up to distances $\sim 10^5 m$ (atmospheric electrostatic discharges) while magnetic fields have been observed in distances $\sim 10^{20} m$ (cosmic magnetic fields).

1.2 Maxwell Equations

The description and evolution of electric and magnetic fields in vacuum is given by Maxwell equations,

$$\nabla \cdot \mathbf{E} = \frac{\rho}{\epsilon_0} \quad (1.22)$$

$$\nabla \times \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t} \quad (1.23)$$

$$\nabla \cdot \mathbf{B} = 0 \quad (1.24)$$

$$\nabla \times \mathbf{B} = \mu_0 \mathbf{j} + \mu_0 \epsilon_0 \frac{\partial \mathbf{E}}{\partial t} \quad (1.25)$$

where

$$\epsilon_0 = 8.854 \times 10^{-12} \text{ F/m} \quad (1.26)$$

is called the *permittivity of free space* and

$$\mu_0 = \frac{1}{\epsilon_0 c^2} \quad (1.27)$$

is the *permeability of free space*.

1.3 Maxwell Equations in Matter

We introduce the notion of "free" densities of charge and current,

$$\rho_f = \rho_f(t, \mathbf{r}) \quad (1.28)$$

$$\mathbf{j}_f = \mathbf{j}_f(t, \mathbf{r}), \quad (1.29)$$

which will produce electric and magnetic fields contributing to the total fields in a given region of space. The *polarization* of a dielectric is characterized by a vector

$$\mathbf{P} = \mathbf{P}(t, \mathbf{r}) \quad (1.30)$$

while the *magnetization* of a magnet is characterized by a vector

$$\mathbf{M} = \mathbf{M}(t, \mathbf{r}). \quad (1.31)$$

In order to incorporate these quantities into Maxwell equations we use the relations

$$\rho(t, \mathbf{r}) = \rho_f(t, \mathbf{r}) - \nabla \cdot \mathbf{P}(t, \mathbf{r}) \quad (1.32)$$

and

$$\mathbf{j}(t, \mathbf{r}) = \mathbf{j}_f(t, \mathbf{r}) + \nabla \times \mathbf{M}(t, \mathbf{r}) + \frac{\partial \mathbf{P}(t, \mathbf{r})}{\partial t}. \quad (1.33)$$

We also define the auxiliary macroscopic fields

$$\mathbf{D}(t, \mathbf{r}) = \epsilon_0 \mathbf{E}(t, \mathbf{r}) + \mathbf{P}(t, \mathbf{r}) \quad (1.34)$$

and

$$\mathbf{H}(t, \mathbf{r}) = \frac{\mathbf{B}(t, \mathbf{r})}{\mu_0} - \mathbf{M}(t, \mathbf{r}). \quad (1.35)$$

Hence, using these definitions, the first of Maxwell equations (1.22) writes

$$\nabla \cdot \mathbf{E} = \frac{\rho}{\epsilon_0} \quad (1.36)$$

$$\nabla \cdot \left(\frac{\mathbf{D} - \mathbf{P}}{\epsilon_0} \right) = \frac{\rho_f - \nabla \cdot \mathbf{P}}{\epsilon_0} \quad (1.37)$$

$$\nabla \cdot \mathbf{D} = \rho_f. \quad (1.38)$$

Similarly, equation (1.25) becomes

$$\nabla \times \mathbf{B} = \mu_0 \mathbf{j} + \mu_0 \epsilon_0 \frac{\partial \mathbf{E}}{\partial t} \quad (1.39)$$

$$\mu_0 \nabla \times (\mathbf{H} + \mathbf{M}) = \mu_0 \left(\mathbf{j}_f(t, \mathbf{r}) + \nabla \times \mathbf{M}(t, \mathbf{r}) + \frac{\partial \mathbf{P}(t, \mathbf{r})}{\partial t} \right) + \mu_0 \epsilon_0 \frac{\partial \mathbf{E}}{\partial t}$$

$$\nabla \times \mathbf{H} = \mathbf{j}_f + \frac{\partial \mathbf{D}}{\partial t} \quad (1.40)$$

Therefore, we conclude that Maxwell equations in matter are written as

$$\nabla \cdot \mathbf{D} = \rho_f \quad (1.41)$$

$$\nabla \times \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t} \quad (1.42)$$

$$\nabla \cdot \mathbf{B} = 0 \quad (1.43)$$

$$\nabla \times \mathbf{H} = \mathbf{j}_f + \frac{\partial \mathbf{D}}{\partial t} \quad (1.44)$$

Chapter 2

Electrostatics

From Maxwell equations (1.22 - 1.25), every time-independent charge distribution $\rho(\mathbf{r})$ will produce an electric vector field independent of time, $\mathbf{E}(\mathbf{r})$, described by the equations

$$\nabla \cdot \mathbf{E} = \rho \quad (2.1)$$

and

$$\nabla \times \mathbf{E} = 0. \quad (2.2)$$

Given a charge distribution represented by the density $\tilde{\rho}(\mathbf{r})$, the electric field $\mathbf{E}(\mathbf{r})$ will exert on it a force given by

$$\mathbf{F} = \int \tilde{\rho}(\mathbf{r}) \mathbf{E}(\mathbf{r}) d^3r \quad (2.3)$$

and a torque given by

$$\mathbf{N} = \int \mathbf{r} \times [\tilde{\rho}(\mathbf{r}) \mathbf{E}(\mathbf{r})] d^3r. \quad (2.4)$$

2.1 Helmholtz Theorem

Helmholtz Theorem guarantees that equations (2.1) and (2.2) determines the field $\mathbf{E}(\mathbf{r})$ uniquely.

Statement of the Theorem

Any arbitrary vector field $\mathbf{E}(\mathbf{r})$ can always be decomposed into the sum of two vector fields, one with zero divergence and one with zero curl,

$$\mathbf{E} = \mathbf{E}_\perp + \mathbf{E}_\parallel, \quad (2.5)$$

where

$$\nabla \cdot \mathbf{E}_\perp = 0 \quad (2.6)$$

$$\nabla \times \mathbf{E}_\parallel = 0 \quad (2.7)$$

2.2 Scalar Potential

Equation (2.2) states that the electrostatic field is conservative, so that it can be derived from the gradient of some scalar function (because the curl of any well-behaved scalar function vanishes). This function is called the *scalar potential* and hence

$$\mathbf{E} = -\nabla\Phi. \quad (2.8)$$

2.3 Poisson and Laplace Equations

Using the scalar potential defined in Eq. (2.8) in Maxwell equation for the electrostatic field, (2.1), gives one partial differential for $\Phi(\mathbf{r})$ called the *Poisson equation*,

$$\nabla^2\Phi = -\frac{\rho}{\epsilon_0}. \quad (2.9)$$

In a region of space with no electric charge, this equation reduces to the *Laplace equation*,

$$\nabla^2\Phi = 0. \quad (2.10)$$

2.4 Coulomb Field

A particular solution of Maxwell equations is given by Coulomb's field, which has been experimentally established in the 18th century by Priestley, Cavendish and Coulomb. It is defined by Coulomb's law, which gives the force acting on a charge q due to n point charges q_i located at positions \mathbf{r}_i ,

$$\mathbf{F} = q\mathbf{E}, \quad (2.11)$$

where

$$\mathbf{F} = \frac{1}{4\pi\epsilon_0} \sum_{i=1}^n qq_i \frac{\mathbf{r} - \mathbf{r}_i}{|\mathbf{r} - \mathbf{r}_i|^3}. \quad (2.12)$$

Thus, Coulomb's electrostatic field in vacuum is

$$\mathbf{E} = \frac{1}{4\pi\epsilon_0} \sum_{i=1}^n q_i \frac{\mathbf{r} - \mathbf{r}_i}{|\mathbf{r} - \mathbf{r}_i|^3}, \quad (2.13)$$

where the proportionality constant has the value

$$k = \frac{1}{4\pi\epsilon_0} = 10^{-7}c^2. \quad (2.14)$$

For a general charge density $\rho(\mathbf{r}')$ the electrostatic Coulomb's field is

$$\mathbf{E} = \frac{1}{4\pi\epsilon_0} \int \rho(\mathbf{r}') \frac{\mathbf{r} - \mathbf{r}'}{|\mathbf{r} - \mathbf{r}'|^3} d^3r', \quad (2.15)$$

Since

$$\frac{\mathbf{r} - \mathbf{r}'}{|\mathbf{r} - \mathbf{r}'|^3} = -\nabla \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) \quad (2.16)$$

we can write Coulomb's field (2.15) as

$$\mathbf{E} = -\frac{1}{4\pi\epsilon_0} \nabla \int \frac{\rho(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3r', \quad (2.17)$$

and therefore, the scalar potential for the Coulomb's field is written

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int \frac{\rho(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3r'. \quad (2.18)$$

In order to show that this potential is a solution of Poisson equation, consider each term in the integral, $\frac{1}{|\mathbf{r} - \mathbf{r}'|}$, which can be written as $\frac{1}{r}$ by choosing coordinates such that $\mathbf{r}' = 0$. In cartesian coordinates we have $\mathbf{r} = x^1 \hat{\mathbf{n}}_1 + x^2 \hat{\mathbf{n}}_2 + x^3 \hat{\mathbf{n}}_3$ and $r = \sqrt{(x^1)^2 + (x^2)^2 + (x^3)^2}$. Therefore, for $\mathbf{r} \neq 0$,

$$\frac{\partial r}{\partial x^j} = \frac{\partial}{\partial x^j} \sqrt{(x^1)^2 + (x^2)^2 + (x^3)^2} = \frac{x^j}{r} = n^j \quad (2.19)$$

and

$$\frac{\partial n^j}{\partial x^k} = \frac{\partial}{\partial x^k} \left(\frac{x^j}{r} \right) = \frac{\delta_{jk}}{r} - \frac{x^j}{r^2} \frac{\partial r}{\partial x^k} = \frac{1}{r} [\delta_{jk} - n^j n^k]. \quad (2.20)$$

These relations let us write the derivative

$$\frac{\partial}{\partial x^j} \left(\frac{1}{r} \right) = -\frac{1}{r^2} \frac{\partial r}{\partial x^j} = -\frac{n^j}{r^2} \quad (2.21)$$

and the second derivative

$$\frac{\partial^2}{\partial x^k \partial x^j} \left(\frac{1}{r} \right) = \frac{\partial}{\partial x^k} \left(-\frac{n^j}{r^2} \right) = -\frac{1}{r^2} \frac{\partial n^j}{\partial x^k} + 2 \frac{n^j}{r^3} \frac{\partial r}{\partial x^k} \quad (2.22)$$

$$\frac{\partial^2}{\partial x^k \partial x^j} \left(\frac{1}{r} \right) = -\frac{1}{r^2} \frac{1}{r} [\delta_{jk} - n^j n^k] + 2 \frac{n^j}{r^3} n^k \quad (2.23)$$

$$\frac{\partial^2}{\partial x^k \partial x^j} \left(\frac{1}{r} \right) = \frac{1}{r^3} [3n^j n^k - \delta_{jk}]. \quad (2.24)$$

Thus, the Laplacian for $\mathbf{r} \neq 0$ is given by

$$\nabla^2 \left(\frac{1}{r} \right) = \frac{\partial^2}{\partial x^k \partial x^k} \left(\frac{1}{r} \right) = \frac{1}{r^3} [3n^k n^k - \delta_{kk}] = 0. \quad (2.25)$$

The behavior at $\mathbf{r} = 0$ is studied by integrating the term $\nabla^2 \left(\frac{1}{r} \right)$ over a tiny spherical volume V centered at the origin. In this case the divergence theorem gives

$$\int_V \left(\nabla^2 \frac{1}{r} \right) d^3r = \int_V \nabla \cdot \left(\nabla \frac{1}{r} \right) d^3r = \oint_S \left(\nabla \frac{1}{r} \right) \cdot d\mathbf{S} = - \oint_S \frac{\hat{\mathbf{r}}}{r^2} \cdot d\mathbf{S}. \quad (2.26)$$

Since the volume is a sphere, the surface element is $d\mathbf{S} = r^2 \sin^2 \theta d\theta d\varphi \hat{\mathbf{r}}$. Thus,

$$\int_V \left(\nabla^2 \frac{1}{r} \right) d^3r = - \int_0^{2\pi} d\varphi \int_0^\pi \sin \theta d\theta = -4\pi. \quad (2.27)$$

These results can be summarized in the expression

$$\int_V \left(\nabla^2 \frac{1}{r} \right) d^3r = \begin{cases} 0 & \text{if } r \neq 0 \\ -4\pi & \text{if } r = 0 \end{cases} \quad (2.28)$$

which can be obtained by writing

$$\nabla^2 \frac{1}{r} = -4\pi \delta(\mathbf{r}). \quad (2.29)$$

In general, recovering the term \mathbf{r}' , we have that

$$\nabla^2 \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) = -4\pi \delta(\mathbf{r} - \mathbf{r}'), \quad (2.30)$$

and therefore, replacing this result in the scalar potential (2.8), we recover the Poisson equation,

$$\nabla^2 \Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int \rho(\mathbf{r}') \nabla^2 \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) d^3r' \quad (2.31)$$

$$\nabla^2 \Phi(\mathbf{r}) = -\frac{1}{4\pi\epsilon_0} \int \rho(\mathbf{r}') 4\pi \delta(\mathbf{r} - \mathbf{r}') d^3r' \quad (2.32)$$

$$\nabla^2 \Phi(\mathbf{r}) = -\frac{\rho(\mathbf{r})}{\epsilon_0}. \quad (2.33)$$

2.5 Potential Energy

The product of a charge times a scalar potential, $U = q\Phi$ is interpreted as the potential energy of that charge in the presence of the corresponding electrostatic field. Similarly, the work done in moving the charge q from a point A to a point B in space against the electric field is given by

$$W = - \int_A^B \mathbf{F} \cdot d\mathbf{l} = -q \int_A^B \mathbf{E} \cdot d\mathbf{l}, \quad (2.34)$$

or in terms of the electrostatic potential

$$W = q \int_A^B \nabla \Phi \cdot d\mathbf{l} = q \int_{\Phi_A}^{\Phi_B} d\Phi = q (\Phi_A - \Phi_B). \quad (2.35)$$

2.6 Discontinuities in the Electric Field and Potential

Suppose a surface S with surface charge density $\sigma(\mathbf{r})$ and with normal unit vector $\hat{\mathbf{n}}$ going from side 1 to side 2 of S . Consider also that the electric field has values \mathbf{E}_1 and \mathbf{E}_2 on each side of the surface. Hence, considering a cylindrical surface crossing S , Gauss' law gives

$$\oint \mathbf{E} \cdot \hat{\mathbf{n}} dS = \frac{1}{\epsilon_0} \int_V \rho d^3x = \frac{1}{\epsilon_0} \int_S \sigma dS \quad (2.36)$$

$$\int_S \mathbf{E}_2 \cdot \hat{\mathbf{n}} dS - \int_S \mathbf{E}_1 \cdot \hat{\mathbf{n}} dS = \frac{1}{\epsilon_0} \int_S \sigma dS \quad (2.37)$$

from which

$$(\mathbf{E}_2 - \mathbf{E}_1) \cdot \hat{\mathbf{n}} = \frac{\sigma}{\epsilon_0}. \quad (2.38)$$

This relation doesn't specify completely the electric field, but tells that there is a discontinuity at the surface due to the charge density σ . On the other hand, the scalar potential can be written in general terms as in equation (2.18), but replacing the density ρ with σ , i.e.

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_S \frac{\sigma(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} dS'. \quad (2.39)$$

2.7 Dipole-Layer Distribution

A dipole-layer corresponds to configuration in which a surface S with charge density $\sigma(\mathbf{r})$ is accompanied of another surface S' with charge density $-\sigma(\mathbf{r})$. If S' approach infinitesimally close to S while $\sigma(\mathbf{r})$ becomes infinite, the product of this charge density and the local separation between surfaces, $d(\mathbf{r})$, corresponds to the *dipole-layer distribution strength*,

$$D(\mathbf{r}) = \lim_{d(\mathbf{r}) \rightarrow 0} \sigma(\mathbf{r})d(\mathbf{r}). \quad (2.40)$$

This quantity has a direction defined as normal to the surface S and in going from the negative to the positive charge.

In order to obtain the scalar potential produce by this configuration we use equation (2.39) to write

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_S \frac{\sigma(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} dS' - \frac{1}{4\pi\epsilon_0} \int_{S'} \frac{\sigma(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}' + \hat{\mathbf{n}}d|} dS'. \quad (2.41)$$

Now, it is possible to expand the integrand in the second term for small d using the expression

$$\frac{1}{|\mathbf{x} - \boldsymbol{\alpha}|} = \frac{1}{x} + \boldsymbol{\alpha} \cdot \boldsymbol{\nabla} \left(\frac{1}{x} \right) + \dots \quad (2.42)$$

when $|\boldsymbol{\alpha}| \ll |\mathbf{x}|$. This gives

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_S \frac{\sigma(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} dS' - \frac{1}{4\pi\epsilon_0} \int_{S'} \sigma(\mathbf{r}') \left[\frac{1}{|\mathbf{r} - \mathbf{r}'|} + d\hat{\mathbf{n}} \cdot \boldsymbol{\nabla} \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) + \dots \right] dS' \quad (2.43)$$

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_{S'} \sigma(\mathbf{r}') d\hat{\mathbf{n}} \cdot \boldsymbol{\nabla} \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) dS' \quad (2.44)$$

and then, in the limit $d \rightarrow 0$, we obtain the dipole-layer distribution strength,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_S D(\mathbf{r}') \hat{\mathbf{n}} \cdot \boldsymbol{\nabla} \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) dS'. \quad (2.45)$$

Note that

$$\hat{\mathbf{n}} \cdot \boldsymbol{\nabla} \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) dS' = -\hat{\mathbf{n}} \cdot \left(\frac{\mathbf{r} - \mathbf{r}'}{|\mathbf{r} - \mathbf{r}'|^3} \right) dS' = -\frac{\cos \theta dS'}{|\mathbf{r} - \mathbf{r}'|^2} = -d\Omega, \quad (2.46)$$

where $d\Omega$ is the solid angle swept by dS' as seen from the position \mathbf{r} . Hence, the scalar potential is simply

$$\Phi(\mathbf{r}) = -\frac{1}{4\pi\epsilon_0} \int_S D(\mathbf{r}') d\Omega. \quad (2.47)$$

2.8 Energy Density and Capacitance

If a point charge q_i is brought from infinity to a point \mathbf{r}_i in a region with an electric field described by the potential $\Phi(\mathbf{r}_i)$ (vanishing at infinity), the work done on the charge is

$$W_i = q_i \Phi(\mathbf{r}_i). \quad (2.48)$$

This also corresponds to the potential energy of the charged particle at point \mathbf{r} . If the potential is produced by an array of $(n-1)$ point charges q_j with $j = 1, 2, \dots, n-1$ located at positions \mathbf{r}_j , we can write

$$\Phi(\mathbf{r}_i) = \frac{1}{4\pi\epsilon_0} \sum_{j=1}^{n-1} \frac{q_j}{|\mathbf{r}_i - \mathbf{r}_j|}. \quad (2.49)$$

Hence, we have

$$W_i = \frac{q_i}{4\pi\epsilon_0} \sum_{j=1}^{n-1} \frac{q_j}{|\mathbf{r}_i - \mathbf{r}_j|}. \quad (2.50)$$

If we consider that we add each charge in succession to build the whole system, we sum over i and j (with $i \neq j$) and divide by 2 to obtain the *total potential energy* of the system,

$$W = \frac{1}{8\pi\epsilon_0} \sum_{i=1}^n \sum_{j=1}^n \frac{q_i q_j}{|\mathbf{r}_i - \mathbf{r}_j|}. \quad (2.51)$$

This expression can be generalized to charge distributions as

$$W = \frac{1}{8\pi\epsilon_0} \int \int \frac{\rho(\mathbf{r})\rho(\mathbf{r}')}{|\mathbf{r}_i - \mathbf{r}_j|} d^3x d^3x' \quad (2.52)$$

or as

$$W = \frac{1}{2} \int \rho(\mathbf{r})\Phi(\mathbf{r}) d^3x. \quad (2.53)$$

Using Poisson equation we can write this equation as

$$W = -\frac{\epsilon_0}{2} \int \Phi(\mathbf{r})\nabla^2\Phi(\mathbf{r}) d^3x. \quad (2.54)$$

Since

$$\nabla \cdot (\Phi \nabla \Phi) = |\nabla \Phi|^2 + \Phi \nabla^2 \Phi, \quad (2.55)$$

we have

$$W = -\frac{\epsilon_0}{2} \int [\nabla \cdot (\Phi \nabla \Phi) - |\nabla \Phi|^2] d^3x. \quad (2.56)$$

The first term is zero because the integration is over all space and the potential vanishes at infinity. Therefore we are left with

$$W = \frac{\epsilon_0}{2} \int |\nabla \Phi|^2 d^3x = \frac{\epsilon_0}{2} \int |\mathbf{E}|^2 d^3x. \quad (2.57)$$

The integrand in the last expression is identified with the energy density of the electrostatic field,

$$\mathcal{W} = \frac{\epsilon_0}{2} |\mathbf{E}|^2. \quad (2.58)$$

Example Consider a conductor with a surface charge density σ . Gauss' law gives the field in the surroundings of the conductor as

$$|\mathbf{E}|^2 = \frac{\sigma^2}{\epsilon_0^2}. \quad (2.59)$$

and then

$$\mathcal{W} = \frac{\sigma^2}{2\epsilon_0}. \quad (2.60)$$

If an area element Δa of the conducting surface is displaced outwards in a small distance Δx , the electrostatic energy decreases in the amount

$$\Delta W = -\mathcal{W}\Delta a\Delta x = -\frac{\sigma^2}{2\epsilon_0}\Delta a\Delta x \quad (2.61)$$

2.8.1 Capacitance

Consider a system of n conductors, each with potential V_i and total charge Q_i in empty space. The electrostatic potential energy of this system can be expressed in terms of the potentials and some geometrical quantities called coefficients of capacity. Since the potential is proportional to the electric charge we write

$$V_i = \sum_{j=1}^n p_{ij} Q_j \quad (2.62)$$

where the coefficients p_{ij} depend on the geometry of the conductors. Inverting these n equations we get expressions in the form

$$Q_i = \sum_{j=1}^n C_{ij} V_j \quad (2.63)$$

where the coefficients C_{ii} are called *capacities* or *capacitances* and the terms C_{ij} with $i \neq j$ are called *coefficients of induction*.

The capacitance of a conductor is defined as the total charge on the conductor when it is maintained at unit potential and all other conductors are held at zero potential.

The potential energy for the system of conductors is written as

$$W = \frac{1}{2} \sum_{i=1}^n Q_i V_i = \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n C_{ij} V_i V_j \quad (2.64)$$

2.9 Green's Theorems

Now we will show two identities or theorems due to George Green (1824). The first one uses the divergence theorem, which writes

$$\int_V \nabla \cdot \mathbf{A} d^3x = \oint_S \mathbf{A} \cdot d\mathbf{S} \quad (2.65)$$

for any well-behaved vector field \mathbf{A} . Considering two arbitrary scalar fields ϕ and ψ such that $\mathbf{A} = \phi \nabla \psi$, we have the vector identity

$$\nabla \cdot \mathbf{A} = \nabla \cdot (\phi \nabla \psi) = \phi \nabla^2 \psi + \nabla \phi \cdot \nabla \psi. \quad (2.66)$$

Similarly, writing the surface element as $d\mathbf{S} = \hat{\mathbf{n}} da$, we have

$$\mathbf{A} \cdot d\mathbf{S} = \phi \nabla \psi \cdot d\mathbf{S} = \phi \nabla \psi \cdot \hat{\mathbf{n}} da = \phi \frac{\partial \psi}{\partial n} da, \quad (2.67)$$

where $\frac{\partial}{\partial n}$ represents the normal derivative at the surface S . Replacing these relations in the divergence theorem gives the *Green's first identity*,

$$\int_V [\phi \nabla^2 \psi + \nabla \phi \cdot \nabla \psi] d^3x = \oint_S \phi \frac{\partial \psi}{\partial n} da. \quad (2.68)$$

Considering now the field $\mathbf{A} = \psi \nabla \phi$ gives the relation

$$\int_V [\psi \nabla^2 \phi + \nabla \psi \cdot \nabla \phi] d^3x = \oint_S \psi \frac{\partial \phi}{\partial n} da. \quad (2.69)$$

Subtracting these two relations we obtain the *Green's second identity*,

$$\int_V [\phi \nabla^2 \psi - \psi \nabla^2 \phi] d^3x = \oint_S \left[\phi \frac{\partial \psi}{\partial n} - \psi \frac{\partial \phi}{\partial n} \right] da. \quad (2.70)$$

As a particular example of this theorem, consider the functions

$$\psi = \frac{1}{|\mathbf{r} - \mathbf{r}'|} \quad (2.71)$$

$$\phi = \Phi(\mathbf{r}'). \quad (2.72)$$

This gives

$$\int_V \left[\Phi(\mathbf{r}') \nabla^2 \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) - \frac{1}{|\mathbf{r} - \mathbf{r}'|} \nabla^2 \Phi(\mathbf{r}') \right] d^3x' = \oint_S \left[\Phi \frac{\partial}{\partial n'} \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) - \frac{1}{|\mathbf{r} - \mathbf{r}'|} \frac{\partial \Phi}{\partial n'} \right] da'. \quad (2.73)$$

Using Poisson equation and the Dirac delta function this becomes

$$\int_V \left[-4\pi \Phi(\mathbf{r}') \delta(\mathbf{r} - \mathbf{r}') + \frac{1}{|\mathbf{r} - \mathbf{r}'|} \frac{\rho(\mathbf{r}')}{\epsilon_0} \right] d^3x' = \oint_S \left[\Phi \frac{\partial}{\partial n'} \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) - \frac{1}{|\mathbf{r} - \mathbf{r}'|} \frac{\partial \Phi}{\partial n'} \right] da'. \quad (2.74)$$

If the point \mathbf{r} lies within the volume V the first term is integrated to give

$$-4\pi \Phi(\mathbf{r}) + \int_V \left[\frac{1}{|\mathbf{r} - \mathbf{r}'|} \frac{\rho(\mathbf{r}')}{\epsilon_0} \right] d^3x' = \oint_S \left[\Phi \frac{\partial}{\partial n'} \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) - \frac{1}{|\mathbf{r} - \mathbf{r}'|} \frac{\partial \Phi}{\partial n'} \right] da' \quad (2.75)$$

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_V \frac{\rho(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3x' + \frac{1}{4\pi} \oint_S \left[\frac{1}{|\mathbf{r} - \mathbf{r}'|} \frac{\partial \Phi}{\partial n'} - \Phi \frac{\partial}{\partial n'} \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) \right] da'. \quad (2.76)$$

On the other hand, if the point \mathbf{r} doesn't lie within the volume V we obtain

$$\frac{1}{\epsilon_0} \int_V \frac{\rho(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3x' = \oint_S \left[\Phi \frac{\partial}{\partial n'} \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) - \frac{1}{|\mathbf{r} - \mathbf{r}'|} \frac{\partial \Phi}{\partial n'} \right] da' \quad (2.77)$$

...

2.10 Dirichlet and Neumann Boundary Conditions

In order to specify completely a solution of Poisson or Laplace equation it is necessary to give some boundary conditions. When the value of the potential

on a closed surface is given we are talking about a *Dirichlet boundary condition*. If the value of electric field (normal derivative of the potential) is given on the surface, it is known as a *Neumann boundary condition*.

In order to probe that the solution of the Poisson equations is unique given D- or N- boundary conditions, consider a volume V surrounded by a closed surface S at which boundary conditions are specified. Suppose that there exist two solutions of the Poisson equation, Φ_1 and Φ_2 , satisfying the boundary conditions. Then the quantity

$$\Psi = \Phi_1 - \Phi_2 \quad (2.78)$$

will satisfy the relation

$$\nabla^2 \Psi = \nabla^2 \Phi_1 - \nabla^2 \Phi_2 = -\frac{\rho}{\epsilon_0} + \frac{\rho}{\epsilon_0} = 0 \quad (2.79)$$

inside the volume V . It also satisfies

$$\Psi|_S = \Phi_1|_S - \Phi_2|_S = 0 \quad (2.80)$$

for Dirichlet boundary conditions or

$$\left. \frac{\partial \Psi}{\partial n} \right|_S = \left. \frac{\partial \Phi_1}{\partial n} \right|_S - \left. \frac{\partial \Phi_2}{\partial n} \right|_S = 0 \quad (2.81)$$

for Neumann boundary conditions. However, Green's first identity (2.68) give, using $\phi = \psi = \Psi$,

$$\int_V [\Psi \nabla^2 \Psi + \nabla \Psi \cdot \nabla \Psi] d^3x = \oint_S \Psi \frac{\partial \Psi}{\partial n} da \quad (2.82)$$

and reduces for both boundary conditions to

$$\int_V \nabla \Psi \cdot \nabla \Psi d^3x = 0 \quad (2.83)$$

or

$$\int_V |\nabla \Psi|^2 d^3x = 0 \quad (2.84)$$

from which we conclude that $\nabla \Psi = 0$ or equivalently $\Psi = \text{constant}$ inside V . For Dirichlet boundary conditions we have $\Psi = 0$ on S , which implies that $\Phi_1 = \Phi_2$ inside V , i.e. the solution is unique.

On the other hand, for Neumann boundary conditions $\frac{\partial \Psi}{\partial n} = 0$ on S , and after integration it gives $\Phi_1 - \Phi_2 = \text{constant}$ inside V , i.e. the solution is unique apart from an unimportant additive constant.

2.11 Formal Solution of the Poisson Equation with Boundary Conditions. Green Functions

We have shown that

$$\nabla^2 \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) = -4\pi\delta(\mathbf{r} - \mathbf{r}'). \quad (2.85)$$

This is an example of the *Green functions*, which satisfy the equation

$$\nabla^2 G(\mathbf{r}, \mathbf{r}') = -4\pi\delta(\mathbf{r} - \mathbf{r}'). \quad (2.86)$$

In general we can write G as

$$G(\mathbf{r}, \mathbf{r}') = \frac{1}{|\mathbf{r} - \mathbf{r}'|} + F(\mathbf{r}, \mathbf{r}') \quad (2.87)$$

with F a function satisfying

$$\nabla^2 G(\mathbf{r}, \mathbf{r}') = 0 \quad (2.88)$$

inside V . Green's theorem (2.70) let us write the general solution for the potential and the additional freedom given by function F can be used to eliminate one of the two surface integrals in the right hand side of the equation, giving an electrostatic potential satisfying either Dirichlet or Neumann boundary conditions. To show this, let us write equation (2.70) using $\phi = \Phi$ and $\psi = G(\mathbf{r}, \mathbf{r}')$,

$$\int_V [\Phi(\mathbf{r}') \nabla^2 G(\mathbf{r}, \mathbf{r}') - G(\mathbf{r}, \mathbf{r}') \nabla^2 \Phi(\mathbf{r}')] d^3x' = \oint_S \left[\Phi \frac{\partial G(\mathbf{r}, \mathbf{r}')}{\partial n'} - G(\mathbf{r}, \mathbf{r}') \frac{\partial \Phi}{\partial n'} \right] da' \quad (2.89)$$

$$\int_V \left[-4\pi\Phi(\mathbf{r}')\delta(\mathbf{r} - \mathbf{r}') + G(\mathbf{r}, \mathbf{r}') \frac{\rho(\mathbf{r}')}{\epsilon_0} \right] d^3x' = \oint_S \left[\Phi \frac{\partial G(\mathbf{r}, \mathbf{r}')}{\partial n'} - G(\mathbf{r}, \mathbf{r}') \frac{\partial \Phi}{\partial n'} \right] da' \quad (2.90)$$

$$-4\pi\Phi(\mathbf{r}) + \int_V G(\mathbf{r}, \mathbf{r}') \frac{\rho(\mathbf{r}')}{\epsilon_0} d^3x' = \oint_S \left[\Phi \frac{\partial G(\mathbf{r}, \mathbf{r}')}{\partial n'} - G(\mathbf{r}, \mathbf{r}') \frac{\partial \Phi}{\partial n'} \right] da' \quad (2.91)$$

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_V \rho(\mathbf{r}') G(\mathbf{r}, \mathbf{r}') d^3x' + \frac{1}{4\pi} \oint_S \left[G(\mathbf{r}, \mathbf{r}') \frac{\partial \Phi}{\partial n'} - \Phi \frac{\partial G(\mathbf{r}, \mathbf{r}')}{\partial n'} \right] da'. \quad (2.92)$$

For Dirichlet boundary conditions, we choose the function F so that

$$G_D(\mathbf{r}, \mathbf{r}') = 0 \quad (2.93)$$

for \mathbf{x}' on S . Hence, the first term in the surface integral vanishes and the solution is

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_V \rho(\mathbf{r}') G_D(\mathbf{r}, \mathbf{r}') d^3x' - \frac{1}{4\pi} \oint_S \Phi \frac{\partial G_D(\mathbf{r}, \mathbf{r}')}{\partial n'} da'. \quad (2.94)$$

On the other hand, for Neumann boundary conditions we must take another fact into account. Note that Gauss's theorem applied to the volume integral of equation (2.86) over the whole space gives

$$\int_V \nabla^2 G(\mathbf{r}, \mathbf{r}') d^3 x' = -4\pi \int \delta(\mathbf{r} - \mathbf{r}') d^3 x' \quad (2.95)$$

$$\int_V \nabla \cdot \nabla G(\mathbf{r}, \mathbf{r}') d^3 x' = -4\pi \quad (2.96)$$

$$\oint_S \nabla G(\mathbf{r}, \mathbf{r}') \cdot \mathbf{dS}' = -4\pi \quad (2.97)$$

$$\oint_S \frac{\partial G(\mathbf{r}, \mathbf{r}')}{\partial n'} da' = -4\pi. \quad (2.98)$$

Therefore, the condition that we will impose to obtain Neumann boundary conditions will be

$$\frac{\partial G_N(\mathbf{r}, \mathbf{r}')}{\partial n'} = -\frac{4\pi}{S} \quad (2.99)$$

for \mathbf{x}' on S . Hence the general solution becomes this time

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_V \rho(\mathbf{r}') G(\mathbf{r}, \mathbf{r}') d^3 x' + \frac{1}{4\pi} \oint_S G(\mathbf{r}, \mathbf{r}') \frac{\partial \Phi}{\partial n'} da' + \frac{1}{S} \oint_S \Phi da' \quad (2.100)$$

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \int_V \rho(\mathbf{r}') G(\mathbf{r}, \mathbf{r}') d^3 x' + \frac{1}{4\pi} \oint_S G(\mathbf{r}, \mathbf{r}') \frac{\partial \Phi}{\partial n'} da' + \langle \Phi \rangle_S, \quad (2.101)$$

where

$$\langle \Phi \rangle_S = \frac{1}{S} \oint_S \Phi da' \quad (2.102)$$

is the average value of the potential over the whole surface.

In order to give a physical meaning for the function $F(\mathbf{r}, \mathbf{r}')$, note that it is a

solution of the Laplace equation inside V , so it represents the potential of a system of charges *external to the volume* V . This external distribution of charges is chosen to satisfy the homogeneous boundary conditions of zero potential or zero normal derivative on the surface S (D- or N- boundary conditions) when combined with the other term to give the total potential. This interpretation will be important in the method of images, which will be equivalent to find the appropriate function $F(\mathbf{r}, \mathbf{r}')$ to satisfy the boundary conditions.

2.12 Variational Approach to Poisson Equation and Boundary Conditions

Consider the integral functional,

$$I[\psi] = \frac{1}{2} \int_V \nabla \psi \cdot \nabla \psi d^3 x - \int_V g \psi d^3 x, \quad (2.103)$$

where $\psi(\mathbf{r})$ is a well behaved function inside V and on the boundary surface S while $g(\mathbf{r})$ is a "source" function without singularities within V . Making the infinitesimal transformation $\psi \rightarrow \psi + \delta\psi$, we obtain

$$\delta I = \int_V \nabla\psi \cdot \nabla(\delta\psi) d^3x - \int_V g\delta\psi d^3x + \mathcal{O}(\delta\psi^2). \quad (2.104)$$

Using Green's first identity (2.68) with $\phi = \delta\psi$ and $\psi = \psi$ gives

$$\delta I = \int_V [-\nabla^2\psi] \delta\psi d^3x + \oint_S \delta\psi \frac{\partial\psi}{\partial n} da - \int_V g\delta\psi d^3x + \mathcal{O}(\delta\psi^2) \quad (2.105)$$

$$\delta I = \int_V [-\nabla^2\psi - g] \delta\psi d^3x + \oint_S \delta\psi \frac{\partial\psi}{\partial n} da + \mathcal{O}(\delta\psi^2). \quad (2.106)$$

If $\delta\psi = 0$ on the boundary surface, the second integral vanishes and we conclude that δI vanishes to first order in $\delta\psi$ if

$$\nabla^2\psi = -g. \quad (2.107)$$

Hence, this variational derivation gives Poisson equation for electrostatics if we chose $\psi = \Phi$ and $g = \frac{\rho}{\epsilon_0}$. Note that Dirichlet's boundary conditions are given by the assumed condition $\delta\psi = \delta\Phi = 0$ on the boundary surface S .

In order to obtain the Poisson equation together with the Neumann boundary conditions we use the integral functional

$$I[\psi] = \frac{1}{2} \int_V \nabla\psi \cdot \nabla\psi d^3x - \int_V g\psi d^3x - \oint_S f\psi da, \quad (2.108)$$

and we suppose that the boundary conditions on ψ are given by

$$\left. \frac{\partial\psi}{\partial n} \right|_S = f(\mathbf{s}) \quad (2.109)$$

with s a point on the surface S . Considering the infinitesimal transformation $\psi \rightarrow \psi + \delta\psi$ and Green's first identity as before, we obtain

$$\delta I = \int_V [-\nabla^2\psi - g] \delta\psi d^3x + \oint_S \left[\frac{\partial\psi}{\partial n} - f(\mathbf{s}) \right] \delta\psi da + \mathcal{O}(\delta\psi^2). \quad (2.110)$$

Thus, it is clear that requiring that $\delta I = 0$ independently of $\delta\psi$ implies that

$$\nabla^2\psi = -g \text{ within } V \quad (2.111)$$

and

$$\left. \frac{\partial\psi}{\partial n} \right|_S = f(\mathbf{s}) \text{ on } S. \quad (2.112)$$

Chapter 3

Boundary Value Problems in Electrostatics

3.1 Method of Images

The *Method of Images* works for problems in which there is one (or more) point charges in the presence of boundary surfaces. The method is based in the fact that, under some favorable conditions, it is possible to infer from the given geometry that a small number of charges, called *image charges*, with appropriate magnitudes and location (out of the region of interest) can simulate the required boundary conditions. Since the image charges are external to the volume of interest, their potentials are solution of Laplace's equation inside that volume.

3.1.1 Point Charge in the Presence of a Grounded Infinite Conductor Plane

As shown in the Figure, consider a point charge located at a position $\mathbf{r}' = \ell = \ell \mathbf{e}_1$ in front of a vertical infinite conductor plane at zero potential. Hence, the Dirichlet boundary condition are $\Phi = 0$ at the points in the line $x = 0$ and $\Phi = 0$ at $\{x \rightarrow \infty, y \rightarrow \pm\infty, z \rightarrow \pm\infty\}$. From the geometry, it is easy to infer that this problem is equivalent to the problem of the original point charge together with an equal and opposite charge located at the mirror-image point $\mathbf{r}'_I = -\ell$, behind the conductor surface. Therefore, the potential at any point \mathbf{r} is given by the superposition

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \frac{q}{|\mathbf{r} - \mathbf{r}'|} - \frac{1}{4\pi\epsilon_0} \frac{q}{|\mathbf{r} - \mathbf{r}'_I|}. \quad (3.1)$$

Here we identify the Green function

$$G(\mathbf{r}, \mathbf{r}') = \frac{1}{|\mathbf{r} - \mathbf{r}'|} - \frac{1}{|\mathbf{r} - \mathbf{r}'_I|} \quad (3.2)$$

in the region with $x \geq 0$. Note that this functions satisfies the imposed Dirichlet boundary conditions . It is also possible to identify that the method of images fixes the function $F(\mathbf{r}, \mathbf{r}')$ as

$$F(\mathbf{r}, \mathbf{r}') = -\frac{1}{|\mathbf{r} - \mathbf{r}'_I|}. \quad (3.3)$$

3.1.2 Finite Line of Charge

3.1.3 Point Charge in the Presence of a Grounded Conducting Sphere

Consider a point charge q located at the position \mathbf{r} relative to the origin, around which is centered a grounded conducting sphere of radius R . We want to find the potential $\Phi(\mathbf{r})$ subject to the boundary conditions $\Phi(r = R) = 0$ and $\Phi(r \rightarrow \infty) = 0$. We will assume that it is needed only one image charge q_I lying on the ray going from the origin to the charge q . If q lies outside the sphere, the position \mathbf{r}'_I of the image charge lies inside the sphere. Hence the potential due to both charges is given by

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \frac{q}{|\mathbf{r} - \mathbf{r}'|} + \frac{1}{4\pi\epsilon_0} \frac{q_I}{|\mathbf{r} - \mathbf{r}'_I|}, \quad (3.4)$$

but we must chose q_I and \mathbf{r}'_I to satisfy the boundary conditions. Define the unit vectors \mathbf{n} along the direction \mathbf{r} and \mathbf{n}' along \mathbf{r}' . The we have

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \frac{q}{|r\mathbf{n} - r'\mathbf{n}'|} + \frac{1}{4\pi\epsilon_0} \frac{q_I}{|r\mathbf{n} - r'_I\mathbf{n}'|}. \quad (3.5)$$

Factorizing r in the first term and r'_I in the second, we obtain

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \frac{q}{r|\mathbf{n} - \frac{r'}{r}\mathbf{n}'|} + \frac{1}{4\pi\epsilon_0} \frac{q_I}{r'_I\left|\frac{r}{r'_I}\mathbf{n} - \mathbf{n}'\right|}, \quad (3.6)$$

and evaluating at the conductor sphere, $r = R$, yields

$$\Phi(r = R) = \frac{1}{4\pi\epsilon_0} \left[\frac{q}{R|\mathbf{n} - \frac{r'}{R}\mathbf{n}'|} + \frac{q_I}{r'_I\left|\frac{R}{r'_I}\mathbf{n} - \mathbf{n}'\right|} \right] = 0. \quad (3.7)$$

In order to satisfy this boundary condition, we choose

$$\frac{q_I}{r'_I} = -\frac{q}{R} \quad (3.8)$$

and

$$\frac{R}{r'_I} = \frac{r'}{R}. \quad (3.9)$$

These relations are combined to obtain the image charge

$$q_I = -\frac{R}{r'}q \quad (3.10)$$

and its position

$$r'_I = \frac{R^2}{r'}. \quad (3.11)$$

If the charge q is brought closer to the sphere (i.e. $r' \rightarrow R$) the image charge grows in magnitude, $q_I \rightarrow -q$, and it moves to the center of the sphere, $r'_I \rightarrow R$.

The surface charge density in the conducting sphere is calculated using the image charge and the normal derivative of the potential at the surface (remember that $\mathbf{E} \cdot \mathbf{n} = -\nabla\Phi \cdot \mathbf{n} = \frac{\sigma}{\epsilon_0}$),

$$\sigma = -\epsilon_0 \nabla\Phi \cdot \mathbf{n}|_{r=R} = -\frac{1}{4\pi} \nabla \left[\frac{q}{|\mathbf{r}\mathbf{n} - r'\mathbf{n}'|} + \frac{q_I}{|\mathbf{r}\mathbf{n} - r'_I\mathbf{n}'|} \right] \cdot \mathbf{n} \Big|_{r=R} \quad (3.12)$$

$$\sigma = \frac{1}{4\pi} \left[\frac{q(\mathbf{r}\mathbf{n} - r'\mathbf{n}') \cdot \mathbf{n}}{|\mathbf{r}\mathbf{n} - r'\mathbf{n}'|^3} + \frac{q_I(\mathbf{r}\mathbf{n} - r'_I\mathbf{n}') \cdot \mathbf{n}}{|\mathbf{r}\mathbf{n} - r'_I\mathbf{n}'|^3} \right] \Big|_{r=R} \quad (3.13)$$

$$\sigma = \frac{1}{4\pi} \left[\frac{qr}{|\mathbf{r}\mathbf{n} - r'\mathbf{n}'|^3} + \frac{q_I r}{|\mathbf{r}\mathbf{n} - r'_I\mathbf{n}'|^3} \right] \Big|_{r=R} \quad (3.14)$$

$$\sigma = \frac{1}{4\pi} \left[\frac{qr}{(r^2 + r'^2 - 2rr'\mathbf{n} \cdot \mathbf{n}')^{3/2}} + \frac{q_I r}{(r^2 + r_I'^2 - 2rr'_I\mathbf{n} \cdot \mathbf{n}')^{3/2}} \right] \Big|_{r=R} \quad (3.15)$$

$$\sigma = \frac{1}{4\pi} \left[\frac{qR}{(R^2 + r'^2 - 2Rr'\mathbf{n} \cdot \mathbf{n}')^{3/2}} + \frac{q_I R}{(R^2 + r_I'^2 - 2Rr'_I\mathbf{n} \cdot \mathbf{n}')^{3/2}} \right]. \quad (3.16)$$

Replacing the values of q_I and r'_I we have

$$\sigma = \frac{qR}{4\pi} \left[\frac{1}{(R^2 + r'^2 - 2Rr'\mathbf{n} \cdot \mathbf{n}')^{3/2}} - \frac{\frac{R}{r'}}{\left(R^2 + \left(\frac{R^2}{r'}\right)^2 - 2R\left(\frac{R^2}{r'}\right)\mathbf{n} \cdot \mathbf{n}'\right)^{3/2}} \right] \quad (3.17)$$

$$\sigma = \frac{qR}{4\pi} \left[\frac{1}{r'^3 \left(\left(\frac{R}{r'}\right)^2 + 1 - 2\frac{R}{r'}\mathbf{n} \cdot \mathbf{n}'\right)^{3/2}} - \frac{\frac{R}{r'}}{R^3 \left(1 + \left(\frac{R}{r'}\right)^2 - 2\left(\frac{R}{r'}\right)\mathbf{n} \cdot \mathbf{n}'\right)^{3/2}} \right] \quad (3.18)$$

$$\sigma = \frac{qR}{4\pi} \frac{1}{\left(1 + \left(\frac{R}{r'}\right)^2 - 2\frac{R}{r'}\mathbf{n} \cdot \mathbf{n}'\right)^{3/2}} \left[\frac{1}{r'^3} - \frac{1}{R^2 r'} \right] \quad (3.19)$$

$$\sigma = \frac{qR}{4\pi} \frac{R}{r'} \frac{1}{\left(1 + \left(\frac{R}{r'}\right)^2 - 2\frac{R}{r'}\mathbf{n} \cdot \mathbf{n}'\right)^{3/2}} \left[\frac{1}{r'^2 R} - \frac{1}{R^3} \right] \quad (3.20)$$

$$\sigma = -\frac{q}{4\pi R^2} \frac{R}{r'} \frac{\left(1 - \frac{R^2}{r'^2}\right)}{\left(1 + \left(\frac{R}{r'}\right)^2 - 2\frac{R}{r'} \mathbf{n} \cdot \mathbf{n}'\right)^{3/2}}. \quad (3.21)$$

Defining $\mathbf{n} \cdot \mathbf{n}' = \cos \gamma$ we write

$$\sigma = -\frac{q}{4\pi R^2} \frac{R}{r'} \frac{\left(1 - \frac{R^2}{r'^2}\right)}{\left(1 + \left(\frac{R}{r'}\right)^2 - 2\frac{R}{r'} \cos \gamma\right)^{3/2}}. \quad (3.22)$$

The force acting on q is calculated using the image charge q_I and the distance between them:

$$r_{qq_I} = r' - r'_I = r' \left(1 - \frac{R^2}{r'^2}\right). \quad (3.23)$$

Hence, this force is simply

$$\mathbf{F} = \frac{1}{4\pi\epsilon_0} \frac{qq_I}{r_{qq_I}^2} \mathbf{n} \quad (3.24)$$

$$\mathbf{F} = \frac{1}{4\pi\epsilon_0} \frac{q \left(-\frac{R}{r'} q\right)}{r'^2 \left(1 - \frac{R^2}{r'^2}\right)^2} \mathbf{n} \quad (3.25)$$

$$\mathbf{F} = -\frac{1}{4\pi\epsilon_0} \frac{q^2}{R^2} \left(\frac{R}{r'}\right)^3 \left(1 - \frac{R^2}{r'^2}\right)^{-2} \mathbf{n}. \quad (3.26)$$

If the point charge q lies inside the sphere, the the same results apply.

3.1.4 Point Charge in the Presence of a Charged, Insulated, Conducting Sphere

In order to obtain the potential due to a point charge q near a charged, insulated, conducting sphere we begin with the result of the previous section in which the grounded conducting sphere acquires a total charge of q_I distributed on its surface. The the ground is disconnected and we add to the sphere the charge $(Q - q_I)$ which will bring the total charge of the sphere up to Q . However, we may think as if this added charge will simply distribute uniformly over the surface of the sphere (because the external point charge q is already balanced by the image q_I). Therefore, the total potential is obtained by adding the potential found in the previous section, (3.4), and the potential of a point charge $(Q - q_I)$ at the origin. This gives

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \frac{q}{|\mathbf{r} - \mathbf{r}'|} + \frac{1}{4\pi\epsilon_0} \frac{q_I}{|\mathbf{r} - \mathbf{r}'_I|} + \frac{1}{4\pi\epsilon_0} \frac{Q - q_I}{|\mathbf{r}|} \quad (3.27)$$

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \left[\frac{q}{|\mathbf{r} - \mathbf{r}'|} + \frac{q_I}{|\mathbf{r} - \mathbf{r}'_I|} + \frac{Q - q_I}{|\mathbf{r}|} \right] \quad (3.28)$$

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\epsilon_0} \left[\frac{q}{|\mathbf{r} - \mathbf{r}'|} - \frac{Rq}{r' |\mathbf{r} - \frac{R^2}{r'^2} \mathbf{r}'|} + \frac{Q + \frac{R}{r'} q}{|\mathbf{r}|} \right]. \quad (3.29)$$

Similarly, the force acting on the charge q is obtained by superposition of equation (3.26) with the Coulomb force produced by $(Q - q_I)$,

$$\mathbf{F} = -\frac{1}{4\pi\epsilon_0} \frac{q^2}{R^2} \left(\frac{R}{r'} \right)^3 \left(1 - \frac{R^2}{r'^2} \right)^{-2} \mathbf{n} + \frac{1}{4\pi\epsilon_0} \frac{q(Q - q_I)}{r'^2} \mathbf{n} \quad (3.30)$$

$$\mathbf{F} = -\frac{1}{4\pi\epsilon_0} \frac{q^2}{R^2} \left(\frac{R}{r'} \right)^3 \left(1 - \frac{R^2}{r'^2} \right)^{-2} \mathbf{n} + \frac{1}{4\pi\epsilon_0} \frac{q(Q + \frac{R}{r'} q)}{r'^2} \mathbf{n} \quad (3.31)$$

$$\mathbf{F} = \frac{1}{4\pi\epsilon_0} \frac{q}{r'^2} \left[Q - q \left(\frac{R}{r'} \right) \left(1 - \frac{R^2}{r'^2} \right)^{-2} + \frac{R}{r'} q \right] \mathbf{n} \quad (3.32)$$

$$\mathbf{F} = \frac{1}{4\pi\epsilon_0} \frac{q}{r'^2} \left[Q - q \left(\frac{R}{r'} \right) \left(\left(1 - \frac{R^2}{r'^2} \right)^{-2} - 1 \right) \right] \mathbf{n} \quad (3.33)$$

$$\mathbf{F} = \frac{1}{4\pi\epsilon_0} \frac{q}{r'^2} \left[Q - q \left(\frac{R}{r'} \right) \frac{1 - \left(1 - \frac{R^2}{r'^2} \right)^2}{\left(1 - \frac{R^2}{r'^2} \right)^2} \right] \mathbf{n} \quad (3.34)$$

$$\mathbf{F} = \frac{1}{4\pi\epsilon_0} \frac{q}{r'^2} \left[Q - q \left(\frac{R}{r'} \right) \frac{r'^4 - (r'^2 - R^2)^2}{(r'^2 - R^2)^2} \right] \mathbf{n} \quad (3.35)$$

$$\mathbf{F} = \frac{1}{4\pi\epsilon_0} \frac{q}{r'^2} \left[Q - q \left(\frac{R}{r'} \right) \frac{2r'^2 R^2 - R^4}{(r'^2 - R^2)^2} \right] \mathbf{n} \quad (3.36)$$

$$\mathbf{F} = \frac{1}{4\pi\epsilon_0} \frac{q}{r'^2} \left[Q - q \left(\frac{R^3}{r'} \right) \frac{2r'^2 - R^2}{(r'^2 - R^2)^2} \right] \mathbf{n}. \quad (3.37)$$

Note that in the limit $r' \gg R$ the force reduces to the Coulomb's law,

$$\lim_{r' \gg R} \mathbf{F} = \frac{1}{4\pi\epsilon_0} \frac{qQ}{r'^2} \quad (3.38)$$

Hence, the laplacian in spherical coordinates is written

$$\nabla^2 \Phi = \frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial \Phi}{\partial r} \right) + \frac{1}{r^2 \sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial \Phi}{\partial \theta} \right) + \frac{1}{r^2 \sin^2 \theta} \frac{\partial^2 \Phi}{\partial \varphi^2} \quad (3.39)$$
